

hand_in_module3

January 12, 2024

by Arturas Aleksandraus Hi Vera,

This submission might be a bit different from the others, but I hope you will find it interesting. I'm a very practical person and I like to see and apply theory in practice. I do that by building things. So instead of writing a long essay, I build functions. This helps me to understand the theory better and also to apply it in practice. I had a lot of fun building these functions and I hope you will find my way acceptable.

If you have any questions, please let me know.

If you want to run the code your self you can find it [here](#):

```
[ ]: import numpy as np
      from itertools import product, combinations, combinations_with_replacement,
      ↪permutations
      from collections import defaultdict
      from tqdm import tqdm
```

(Inductive logic programming in the context of propositional logic) Let p, q, r be propositional variables. Since I find it interesting to apply theory to practice I will try to implement the algorithm in python. My argument for that is that if I can implement it then I probably understand it. I will reason for the answers that the algorithm gives.

Assignment 1

- (a) Suppose that all the formulas $\neg p \vee r$, $\neg q \vee \neg r$ and p are true. Determine the truth values of q and r .

```
[ ]: true_statements = [
      lambda p, q, r: not p or r,
      lambda p, q, r: not q or not r,
      lambda p, q, r: p,
  ]

  # way not try all possible combinations?
  for p, q, r in product([True, False], repeat=3):
      if all(map(lambda f: f(p, q, r), true_statements)):
          print(f"p={p}, q={q}, r={r}")
```

p=True, q=False, r=True

- if p is true then r must be true given true statement $\neg p \rightarrow r$.
- if r is true then q must be false given true statement $\neg q \rightarrow \neg r$.

Answer 1.a q is false and r is true.

(b) Construct a CNF which avoids N and covers E where:

$N = \{(0,1,0), (1,0,0), (1,1,0)\}$ and

$E = \{(0,0,0), (0,0,1), (0,1,1), (1,0,1), (1,1,1)\}$.

Try to simplify as much as possible by removing unnecessary 1 literals (if such exist).

```
[ ]: E = np.array([(0,0,0),(0,0,1),(0,1,1),(1,0,1),(1,1,1)])
N = np.array([(0,1,0),(1,0,0),(1,1,0)])
def covers(cause, statements):
    """
    all positive examples satisfy
    """
    cause = np.array(cause, dtype=bool)
    covered = np.zeros(len(statements), dtype=bool)
    for i, statement in enumerate(statements):
        res = list(map(lambda c, s: c if s else not c, cause, statement))
        covered[i] = any(res)
    return all(covered)

def avoids(cause, statements):
    """
    no negative example satisfy
    """
    cause = np.array(cause, dtype=bool)
    avoided = np.zeros(len(statements), dtype=bool)
    for i, statement in enumerate(statements):
        res = list(map(lambda c, s: c if s else not c, cause, statement))
        avoided[i] = all(res)
    return not any(avoided)

def cause_str(cause):
    cause, idxs = cause
    return '(' + ' '.join(map(lambda i: f'{L[i]}' if cause[i] else f'¬{L[i]}', idxs)) + ')'

L = ['p', 'q', 'r', 's', 't']

def find_H(cause, E, N, maximal=True):
    for cause_size in sorted(range(1, len(E[0])+1), reverse=maximal):
        for idxs in combinations(range(len(E[0])), cause_size):
            curr_cause = [cause[i] for i in idxs]
```

```

        if covers(curr_cause, statements=E[:, idxs]) and avoids(curr_cause,
statements=N[:, idxs]):
            return cause, idxs
        return None, None

def algorithm(E, N, maximal=True):
    """
    Algorithm 1; producing a maximally general set or simplified set of clauses
    H which covers E and avoids N
    (3.3) in Logic_and_probability_7.pdf
    """
    inxs = []
    H = []
    used = set()
    for cause in N:
        cause = [int(not c) for c in cause]
        cause, idxs = find_H(cause, E, N, maximal)
        if cause is not None:
            curr = tuple([cause[i] for i in idxs] + list(idxs))
            if curr in used:
                continue
            used.add(curr)
            H.append(cause)
            inxs.append(idxs)
    return zip(H, inxs)

Fi = algorithm(E, N, maximal=True)
print('Maximally CNF:')
print(' '.join(map(cause_str, Fi)))

Fi = algorithm(E, N, maximal=False)
print('Simplified CNF:')
print(' '.join(map(cause_str, Fi)))

```

Maximally CNF:

$(p \neg q \ r) \ (\neg p \ q \ r) \ (\neg p \ \neg q \ r)$

Simplified CNF:

$(\neg q \ r) \ (\neg p \ r)$

Answer 1.b Algorithm 1 and 2 producing a maximally general set or simplified set of clauses H which covers E and avoids N. (3.3) in Logic_and_probability_7.pdf

1. with Maximally CNF:

$(p \neg q \ r) \ (\neg p \ q \ r) \ (\neg p \ \neg q \ r)$

2. with Simplified CNF:

$(\neg q \ r) \ (\neg p \ r)$

In the rest of the assignments **L** and **M** refer to the language **L** and **L**-structure **M** that we now define. Let $L = \{P, Q, R, S, T\}$ where the relation symbols P, Q, R, S, T have arities 1, 1, 2, 2, 2, respectively.

Let M be the **L**-structure with domain $M = \{1, 2, 3, \dots, 20\}$ and the following interpretations of the relation symbols: $* PM = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$, $* QM = \{1, 2, 3, 4, 5, 11, 12, 13, 14, 15\}$, $* RM = \{(i, j) : i = j, 1 \leq i \leq 5 \text{ and } 1 \leq j \leq 5\}$, $* SM = \{(2, 5), (3, 1), (4, 3), (1, 2), (5, 4), (2, 3), (4, 2), (1, 3), (3, 5), (4, 5)\}$, $* TM = \{(2, 5), (3, 1), (4, 3), (1, 2), (5, 4), (3, 2), (2, 1), (1, 4), (2, 4), (5, 2)\}$.

Inductive logic programming and concept learning

- Would it be fun to implement the algorithm that helps us to learn concepts? Yes!
- Can we use example in the in Logic_and_probability_7.pdf to guide and validate our implementation? Yes!
- Is it harder than just solving the assignments by hand? Yes!
- Is solving the assignments by hand a good idea? Probably Yes!
- Will we implement the algorithm even though it is harder and christmas is coming close? Yes!

Thank your patience. Lets get started!

PS. I will try to add some comments to the code to make it more readable. Don't skip them pls.

```

    name = "D"
    def __init__(self, *args):
        self.args = args
        assert len(args) == D.arity

class G(Base):
    arity = 2
    name = "G"
    def __init__(self, *args):
        self.args = args
        assert len(args) == G.arity

A = ['a', 'b', 'e', 'g', 'h', 'm', 'n', 't']

relations = {'F': {F('m'), F('h'), F('e'), F('n')}, # (i.e. m,n,e, and n
↳are females),
             'P': {P('g', 'm'), P('h', 'm'), P('h', 't'), P('t', 'e'),
↳P('n', 'e'), P('a', 't'), P('e', 'b')}, # (i.e. g is a parent of m, h is a
↳parent of m, and so on)
             'D': {D('m', 'g'), D('m', 'h'), D('e', 't'), D('e', 'n')}, # (i.
↳e. m is a daughter of g)
             'G': {G('h', 'e'), G('n', 'b')}, # (i.e. h is a grandmother of
↳e, n is a grandmother of b)
        }

result = concept_learning(D, A, relations, [F, P, G], extra_variables=0,
↳concept_size=2)
concepts_eq, concepts_imp = parse_result(result)
print('Concepts: Daughters')

for c in concepts_eq:
    print(c)

result = concept_learning(G, A, relations, [F, P, D], extra_variables=1,
↳concept_size=3)
concepts_eq, concepts_imp = parse_result(result)
print('Concepts: Grandmothers')

for c in concepts_eq:
    print(c)
scope()

```

100%| | 6/6 [00:00<00:00, 352.79it/s]

Concepts: Daughters

F(x0) P(x1,x0) <-> D(x0,x1)

0%| | 0/10 [00:00<?, ?it/s]100%| | 10/10 [00:07<00:00,
1.27it/s]

Concepts: Grandmothers

F(x0) P(x0,x2) P(x2,x1) <-> G(x0,x1)

D(x2,x0) F(x0) P(x2,x1) <-> G(x0,x1)

Result:

We found the following concept for Daughters: 1. F(x1) P(x0,x1) <-> D(x0,x1)

This makes sense witch is good!

We found the following concept for Grandmothers:

1. F(x0) P(x2,x1) P(x0,x2) <-> G(x0,x1)
2. F(x0) P(x2,x1) D(x2,x0) <-> G(x0,x1)

That is cool since we found one that was expected and one that was not expected but makes sense.

Ether we are a grandmother to the child of our child or that our mother is a grandmother to our child.

Assignment 2 Learning the concept $R(x,y)$: Find literals $l_1(x,y), \dots, l_n(x,y)$ which do not contain R and such that $M \models \forall x \forall y ((l_1(x,y) \dots l_n(x,y)) \rightarrow R(x,y))$ and $M \not\models \forall x \forall y (l_1(x,y) \dots l_n(x,y))$. Observe that a literal denoted $k(x,y)$ above need not necessarily contain both variables x and y and it may be of the form $x = y$ or $\neg(x = y)$. There may be several possibilities, but to get maximal credit on this assignment you need to find such $l_1(x,y), \dots, l_n(x,y)$ so that

$$M \models \forall x \forall y ((\theta_1(x,y) \wedge \dots \wedge \theta_n(x,y)) \leftrightarrow R(x,y))$$

```
[ ]: relations = {'P': PM, 'Q': QM, 'R': RM, 'S': SM, 'T': TM}

result = concept_learning(R, M, relations, [P, Q, S, T], extra_variables=0,
↪concept_size=4)
concepts_eq, concepts_imp = parse_result(result)
print('Concepts: R')
for c in concepts_eq:
    print(c)
```

100%| | 35/35 [00:14<00:00, 2.41it/s]

Concepts: R

P(x0) P(x1) Q(x0) Q(x1) <-> R(x0,x1)

Answer 2 Concept a that is learned for R is:

$$P(x_0) \wedge P(x_1) \wedge Q(x_0) \wedge Q(x_1) \leftrightarrow R(x_0, x_1)$$

After a solution its easy to see that this is a correct solution. However there might exist other solutions that has a larger set of literals. However the smallest set of literals that gives the correct solution is 4 literals.

Construction of a probabilistic model and inference As previously lets use the course material to guide the implementation and validation of the algorithm. Its int to travel to the land of chapter 5 in Logic_and_probability_7.pdf

Algorithm1 for finding the arrows of a DAG corresponding to a lifted Bayesian network:

```

Set  $k := 1$  and as long as  $k < m$  do:
  For every  $i = 1, \dots, k$ , add an arrow from  $i$  to  $k+1$ .
  Set  $I := \{1, \dots, k\}$ .
  For  $i = 1, \dots, k$  do:
    If  $k+1$  and  $i$  are conditionally independent over  $(j : j \in I \setminus \{i\})$ , then
      remove  $i$  from  $I$  (i.e. set  $I := I \setminus \{i\}$ ) and remove the arrow from  $i$  to  $k+1$ .
    Otherwise
      do nothing.
  Set  $k := k + 1$ .
Next, for every vertex  $k$  with parents  $i_1, \dots, i_s$ , say, one computes the conditional probability
 $\Pr(k = 1 \mid i_1 = b_1, \dots, i_s = b_s)$  for every choice of  $b_1, \dots, b_s \in \{0, 1\}$ .

-----

```

After evaluating the algorithm on the textbook example i feel confident that it has somewhat reasonable chance of working. Let continue with the assignment 3.

Assignment 3 (Learning a Bayesian network) Construct a Bayesian network from M in the way explained in Chapter 5.1 using the following order of the formulas, also viewed as random variables from M^2 to $\{0,1\}$: $P(x), P(y), Q(x), Q(y), R(x, y), S(x, y), T(x, y)$. As explained in Chapter 4, we can identify $P(x)$ with a random variable $P_x: M^2 \rightarrow \{0,1\}$ such that $P_x(a, b) = 1$ if $M \models P(a)$ and $P_x(a, b) = 0$ otherwise. $P(y)$ can be identified with a random variable $P_y: M^2 \rightarrow \{0,1\}$ such that $P_y(a, b) = 1$ if $M \models P(b)$ and $P_y(a, b) = 0$ otherwise. If you need you can use conditions like ' $x = y$ ' or ' $x \neq y$ ' when specifying conditions for conditional probabilities (although we don't view such formulas as vertices of the network).

It is also possible, and acceptable, to construct a lifted Bayesian network with vertices P, Q, R, S, T (considered in this order) as defined in Definition 6.2.1 in my notes. The procedure will be essentially the same and you have to do the same calculations. The resulting lifted Bayesian

network will be similar to the one obtained by the first approach, but not identical since the later has 5 vertices while the first has 7. (In the later approach $P(x)$ and $P(y)$ are identified, and $Q(x)$ and $Q(y)$ are identified.) When determining (conditional) independence you can use the usual mathematical definition of independence, as there is no need for “approximation” in this assignment. Use the counting measure (i.e. uniform probability distribution) $M \rightarrow R$ when determining (conditional) probabilities.

```
[ ]: phi = [
    Target('P', 'x'),
    Target('P', 'y', 1),
    Target('Q', 'x'),
    Target('Q', 'y', 1),
    Target('R', 'x,y'),
    Target('S', 'x,y'),
    Target('T', 'x,y'),
]
basian_network = build_lifted_network(M, phi, relations, arity=2)
basian_network.table()
basian_network.draw()
plt.show()
```

Conditional probabilities:

$(P(x)) = 1/2$

 $(P(y)) = 1/2$

 $(Q(x)) = 1/2$

 $(Q(y)) = 1/2$

 $(S(x,y) \mid P(x) \quad Q(y) \quad Q(x) \quad R(x,y) \quad P(y)) = 1/2$
 $(S(x,y) \mid P(x) \quad Q(y) \quad Q(x) \quad R(x,y) \quad \neg P(y)) = \text{undefined}$
 $(S(x,y) \mid P(x) \quad Q(y) \quad Q(x) \quad \neg R(x,y) \quad P(y)) = \text{undefined}$

 $(S(x,y) \mid P(x) \quad \neg Q(y) \quad Q(x) \quad \neg R(x,y) \quad \neg P(y)) = 0$
 $(S(x,y) \mid P(x) \quad \neg Q(y) \quad \neg Q(x) \quad R(x,y) \quad P(y)) = \text{undefined}$
 $(S(x,y) \mid P(x) \quad \neg Q(y) \quad \neg Q(x) \quad R(x,y) \quad \neg P(y)) = \text{undefined}$
 $(S(x,y) \mid P(x) \quad \neg Q(y) \quad \neg Q(x) \quad \neg R(x,y) \quad P(y)) = 0$
 $(S(x,y) \mid P(x) \quad \neg Q(y) \quad \neg Q(x) \quad \neg R(x,y) \quad \neg P(y)) = 0$
 $(S(x,y) \mid \neg P(x) \quad Q(y) \quad Q(x) \quad R(x,y) \quad P(y)) = \text{undefined}$
 $(S(x,y) \mid \neg P(x) \quad Q(y) \quad Q(x) \quad R(x,y) \quad \neg P(y)) = \text{undefined}$

[illegible]

Answer 3 This was a massive Basian Network. However it make sense, from the previous as-
 signment we learn concept $P(x_0) \wedge P(x_1) \wedge Q(x_0) \wedge Q(x_1) < - > R(x_0, x_1)$ this is present in
 the network and it confirms the equivalence of the concept since the conditional probability of
 $\mu(R(x, y)|Q(y) \wedge P(x) \wedge P(y) \wedge Q(x))$ is 1.

Following up on the rest $R(x, y), S(x, y), T(x, y)$ we can se that there is a lot of state overlap in the
 data and that the dependency are arbitrary and are mostly dependent on the algorithm and the
 order that we used to construct the network.

Incomplete Data Lets start at figure 5.7 in Logic_and_probability_7.pdf and see if we can
 implement the EM algorithm.

```
[ ]: def EM_algorithm(data, p0, iterations=10):
    # lets initialize the parameters
    p = p0
    number_of_variables = len(data)
    truth = len(list(filter(lambda x: x, data)))
    unk = len(list(filter(lambda x: x is None, data)))
    none_truth = len(list(filter(lambda x: not x and x is not None, data)))
```

```

    assert truth + unk + none_truth == number_of_variables, f'{truth} + {unk} + {none_truth} != {number_of_variables}'
    results = [p]
    # lets iterate
    for i in range(iterations):
        # lets compute the expected values
        p = (truth + unk*p)/(number_of_variables)
        results.append(p)
    return results

def compute_likelihood(data):
    truth = len(list(filter(lambda x: x, data)))
    none_truth = len(list(filter(lambda x: not x and x is not None, data)))
    return truth/(truth+none_truth)

```

```

[ ]: customer = ['A', 'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I', 'J', 'K', 'L']
# This is a copy of the table in the figure 5.7 in Logic_and_probability_7.pdf
# where None is unknown
I1C = [True, False, None, True, False, True, True, False, False, None, False, True]
I2C = [False, True, False, True, False, False, True, False, True, True, False, True]
I3C = [True, False, True, True, False, True, None, False, True, True, True, True]

print(' (I1(x))')
data = I1C
p0 = 0.1
res = EM_algorithm(data, p0, iterations=6)
print('EM algorithm:')
print(' -> '.join(map(lambda x: f'{x:.4f}', res)))

print(f'Computed Likelihood:\n{compute_likelihood(data):.4f}')

```

```

(I1(x))
EM algorithm:
0.1000 -> 0.4333 -> 0.4889 -> 0.4981 -> 0.4997 -> 0.4999 -> 0.5000
Computed Likelihood:
0.5000

```

```

[ ]: print(' (I3(x))')
data = I3C
p0 = 0.1
res = EM_algorithm(data, p0, iterations=5)
print('EM algorithm:')
print(' -> '.join(map(lambda x: f'{x:.4f}', res)))

```

```
print(f'Computed Likelihood:\n{compute_likelihood(data):.4f}')
```

(I3(x))

EM algorithm:

0.1000 -> 0.6750 -> 0.7229 -> 0.7269 -> 0.7272 -> 0.7273

Computed Likelihood:

0.7273

```
[ ]: data = list(map(lambda x: all(x), filter(lambda x: not None in x, zip(I3C,
    ↪I1C))))
p0 = 1
i3_i1 = compute_likelihood(data)
i1 = compute_likelihood(I1C)

print(f' (I3(x) | I1(x)) = (I3(x) I1(x)) / (I1(x)) = ({Fraction(i3_i1).
    ↪limit_denominator(100)})/({Fraction(i1).limit_denominator(100)}) =
    ↪{Fraction(i3_i1/i1).limit_denominator(100)})')
```

$(I3(x) | I1(x)) = (I3(x) I1(x)) / (I1(x)) = (4/9)/(1/2) = 8/9$

We can see that the iterative algorithm converges fast. However it is faster to just use the closed form solution.

Lets apply it to the data in the assignment.

Assignment 4 Now assume that for each of the pairs (1,4),(5,10),(14,6) and (3,5) we do not know if it belongs to RM or not, and for each of the pairs (4,3),(1,3) and (6,8) we do not know if it belongs to SM or not, but otherwise all assumptions are as before.

Estimate $(R(x,y))$ (also denoted $(R = 1)$) and $(S(x,y) | R(x,y))$ (also denoted $(S = 1 | R = 1)$) by the methods described in Chapter 5.3.

```
[ ]: print("Estimate (R(x,y))")
all_r = {n: False for n in full_uniq(M, 2)}
all_r.update({n.args: True for n in relations['R']}) # Set the True values
all_r.update({n: None for n in [(1,4),(5,10),(14,6),(3,5)]}) # Set the unknown
    ↪values

res = EM_algorithm(list(all_r.values()), 0.5, iterations=5)
print('EM algorithm:')
print(' -> '.join(map(lambda x: f'{x:.4f}', res)))

print(f'Computed Likelihood:\n{compute_likelihood(list(all_r.values())):.4f}')
```

Estimate $(R(x,y))$

EM algorithm:

0.5000 -> 0.0526 -> 0.0479 -> 0.0479 -> 0.0479 -> 0.0479

Computed Likelihood:

0.0479

```
[ ]: print("Estimate (S(x,y) | R(x,y))")
all_s = {n: False for n in full_uniq(M, 2)}
all_s.update({n.args: True for n in relations['S']}) # Set the True values
all_s.update({n: None for n in [(4,3),(1,3),(6,8)]}) # Set the unknown values

s_r = compute_likelihood(list(map(lambda x: all(x), filter(lambda x: not None,
    ↪in x, zip(all_s.values(), all_r.values())))))
r = compute_likelihood(list(all_r.values()))
print(f' (S(x,y) | R(x,y)) = (S(x,y) R(x,y)) / (R(x,y)) = ({Fraction(s_r).
    ↪limit_denominator(100)})/({Fraction(r).limit_denominator(100)}) = {s_r/r:.
    ↪4f}')
```

```
Estimate (S(x,y) | R(x,y))
(S(x,y) | R(x,y)) = (S(x,y) R(x,y)) / (R(x,y)) = (1/53)/(1/21) = 0.3920
```

Answer 4 Estimating $\mu(R(x,y))$ with 5 iteration of EM algorithm with p_0 of 0.5 gives us the following result:

0.5000 -> 0.0526 -> 0.0479 -> 0.0479 -> 0.0479 -> 0.0479

Computed the likelihood gives us 0.0479

we can see that we have converged to the same result after 2 iterations.

Estimating $\mu(S(x,y)|R(x,y))$ we rewrite the formula to $\frac{\mu(S(x,y)\wedge R(x,y))}{\mu(R(x,y))}$ and we get the following result:

$$\mu(S(x,y)|R(x,y)) = \frac{\mu(S(x,y)\wedge R(x,y))}{\mu(R(x,y))} \approx \frac{1/53}{1/21} \approx 0.3920$$

You have to excuse me for the fraction approximation. I did not want to calculate the fraction by hand.

Assignment 5 (Inference/prediction) Let G denote the Bayesian network constructed in assignment 3. Let $D_n = \{1, \dots, n\}$ be a domain. Let W_n be the set of all L-structures with domain D_n . For each positive integer n , the Bayesian network G determines a probability distribution P_n on W_n in the way explained by examples in sections 4.2.9, 5.2.1 and 5.2.2. (If one uses the approach in Chapter 6 then Definition 6.2.5 tells how G determines a probability distribution on W_n . However, it is important to understand what that definition means in the case of the concrete Bayesian network obtained in assignment 3.) Material on the slides from the lectures may also be of help to understand how one can reason about the distribution P_n on W_n .

Since we are interested in results for large n you can choose some lower bound to n if you need it.

- Suppose that $a, b \in D_n$ and $a = b$. Let $P_n(R(a,b))$ be an abbreviation of $P_n(\{A \in W_n: A \models R(a,b)\})$, and similarly for S in place of R . Determine $P_n(R(a,b))$ and $P_n(S(a,b))$ and show how you get to your conclusions.
- For any first-order sentence ϕ let $P_n(\phi)$ be an abbreviation of $P_n(\{A \in W_n: A \models \phi\})$. Determine $\lim_{n \rightarrow \infty} P_n(\exists x \exists y \exists z (S(x,y) \rightarrow S(x,z)))$ and show how you get your conclusion.

Answer 5a I must be honest with you. I did not understand the topic for this assignment, however i will try to answer it to the best of my ability. But it feels like i am missing some crucial understanding of the topic. Lets not give up! Lets try to solve it!

Determining $Pn(R(a, b))$ given G and $a, b \in Dn$ and $a \neq b$ conditional probabilities, $R(x, y)$ is influenced by $P(x)$, $P(y)$, $Q(x)$, and $Q(y)$. We can calculate $Pn(R(a, b))$ using these influences. Since $\mu(R(x, y) \mid P(y) \wedge Q(x) \wedge P(x) \wedge Q(y)) = 1$, and other conditions lead to $\mu(R(x, y) \mid \dots) = 0$, we only need to consider the scenario where all influencing variables are True.

Since $\mu(P(x)) = \mu(P(y)) = \mu(Q(x)) = \mu(Q(y)) = 1/2$, the probability of all these being true simultaneously is $\frac{1}{2^4} = \frac{1}{16}$. Therefore, $Pn(R(a, b)) = \frac{1}{16}$.

Determining $Pn(S(a, b))$ given G and $a, b \in Dn$ and $a \neq b$ conditional probabilities, $S(x, y)$ is influenced by $P(x)$, $P(y)$, $Q(x)$, $Q(y)$ and $R(x, y)$. We have the following probabilities from the conditional probability tables (CPTs):

$$\mu(P(x) = 1) = \mu(P(y) = 1) = \mu(Q(x) = 1) = \mu(Q(y) = 1) = 1/2$$

$$\mu(R(x, y) = 1) = 1/16$$

The exist one valid scenario where $S(x, y)$ is true and that is when $R(x, y) = 1$ and $\mu(S(x, y) \mid R(x, y)) = 1/2$. Therefore, $Pn(S(a, b)) = \frac{1}{16} * \frac{1}{2} = \frac{1}{32}$.

Answer 5b To be honest im not sure how to start this one. Hopefully i will not need the points from this assignment to pass the course. But if I have to understand this i will allot more material to work with it. This feel a bit to fluffy for me. :(
